

CoCoA: increasing integration_accuracy resolves the error

The same narrow-overlap stress test: $\sigma z = 0.003$ at $z = 0.94087$

Quadrature error relative to integration_accuracy = 4 (1024 nodes per panel)

Default → level 2: 0.52036% → 0.00152% for the affected pair.

A default-versus-refined regression check rejects level 0; level 2 passes 0.01%.

Level 3 vs 4 also passes 0.001% for every pair. Inputs, interpolation and the seven panels stay fixed.

This checks CoCoA covariance-module spectra, not ordinary data-vector integration or universal immunity.
