

Why fixed quadrature points cluster near this peak

The points are prescribed in advance; Gauss-Legendre nodes crowd the ends of every panel.

Here, a predefined panel boundary at $z = 1$ lies close to the integrand peak at $z \approx 0.994$.

A The bin overlap makes a narrow peak

B Two panels meet close to the peak

C All 96 nodes of a single fixed rule

D Actual nodes in the two neighbouring panels

CCL 3.3.3 / GSL 2.7 · $\ell = 355.655882$ · $w_0 = -1.03892727$ · bins 4×5 (one-based) · PR #1313 frozen inputs

CCL initial QAG pass: 4.0225% low. CoCoA covariance-module spectra: default versus refined differs by 0.0016% at this point.

CoCoA uses 7 panels $\times$ 96 nodes here. This is not its ordinary data-vector quadrature; no covariance matrix was computed.
